

bar.

- **C · Collapsed History** — older sets collapse to a readable ribbon (tap to expand), Next Set dominates. This is where the auto-collapse behaviour you asked about lives.

Full rationale — component hierarchy tree, why each section sits where it does, a de-emphasis from→to list, what becomes sticky/fixed, and a six-step low-risk implementation order keyed to your real code (`potentialPRsBySetId` , `getCompactTargetLine` , `RPE_VALUES` , `editSet / deleteSet`).

Recommendation: ship Direction A first (smallest diff to `LiveWorkout.tsx`), add C's ribbon as a second step.

On your collapse question — the design answers it deliberately: collapse the *treatment*, not the *information*. The latest set and any PR set stay full; everything else becomes a glanceable chip ribbon with a count, expandable in one tap — never a disclosure that hides what you lifted.

The phones are lightly interactive — poke the steppers, the set-type toggle, the "+ RPE" chip, and tap Direction C's ribbon to expand it. Want me to push any direction further, or fold this into the live `LiveWorkout.tsx` ?
